**Abstract**

AIM: The purpose of this study was to investigate the usefulness of the neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR), Mean Platelet Volume (MPV) and Red Cell Distribution Width (RDW) in the differential diagnosis and follow-up of patients with Bells Palsy.

**Material and Methods:** Twenty-eight patients diagnosed with Bells Palsy and 28 control patients were included in the study. Serum samples were analysed retrospectively on the initial presentation and the seventh day of admission.

**Results:** On admission, the NLR was 1.7±1.2. The mean absolute neutrophil count was 6100±900/mm\(^3\) in control group. Statistically, significant changes were not observed in NLR, PLR, MPV and RDW measurements in Bells Palsy group compared to House-Brackman Staging.

**Conclusion:** Statistically significant changes in the neutrophil count and NLR were determined in the measurements between Bells Palsy and control group (p = 0.013, p = 0.016 respectively) on admission. A grade of the disease and NLR measurements had no statistically significant connection. RDW value was investigated for the first time in the literature for Bells Palsy patients.

**Introduction**

Bells palsy (idiopathic facial paralysis) is the most common cause of unilateral peripheral facial paralysis. The incidence of the disease is 11-40/100,000 in the literature [1]. Vascular causes, autoimmune diseases and inflammation of the nerve sheath can be the etiological factors of the disease [1].

The neutrophil to lymphocyte ratio (NLR) is a useful marker that demonstrates the general inflammation condition. The presence of an elevated NLR was demonstrated in a follow-up of inflammatory diseases like larynx cancer, chronic hepatitis, Behcet’s disease, Celiac disease and ulcerative colitis [2-4].

Platelet to lymphocyte ratio (PLR) can be used in the follow-up of inflammation and cancer diseases like peripheral vascular system disorders, coronary artery disease, gynecologic and hepatobiliary system malignancies [5, 6].

Mean Platelet Volume (MPV) and Red Cell Distribution Width (RDW) are markers that can be used in general inflammatory and peripheral thrombotic disease in the literature [7]. There are no investigations about Bells Palsy and RDW measures in literature.

In the present study, we aimed to evaluate the NLR, PLR, MPV and RDW differences between the differential diagnosis and follow-ups of Bells Palsy patients. We aimed to investigate the whole markers that can be investigated from the simple blood test in Bells Palsy. RDW value was investigated for the first time in the literature for Bells Palsy patients.
Material and Methods

Patients admitted to the Sakarya Akyazi General Hospital between February 2013 and December 2015 with complaints about acute peripheral Bells Palsy were evaluated retrospectively. The study population comprised 28 patients diagnosed with Bells Palsy and 28 control patients.

Patients underwent general examination, with a neurological and otorhinolaryngological examination. Blood biochemistry and whole blood analysis were performed. Temporal Magnetic Resonance (MR) was performed on all members of the study population. The disease is staged using House-Brackman Staging system. 12 patients were Grade 2, ten patients were Grade 3, three patients were Grade 4 and three patients were Grade 5.

The exclusion criteria comprised the presence of an acute/chronic ear infection history, chronic liver failure, chronic inflammatory immunological disorders, neurological diseases, diabetes mellitus, hypertension, chronic renal failure, acute coronary artery disease, active connective tissue disorder, vasculitis, inflammatory bowel disease and. Patients using drugs such as antidiabetic drugs, steroids, chemotherapy drugs, immunomodulatory drugs, antihistaminic drugs, sedative drugs and analgesics were also excluded. Peripheral venous sampling for whole blood analysis and blood biochemistry was performed between 08:00 and 10:00. Whole blood analyses were performed using the same device (ABOTT CELL DYN 3700). Whole blood analyses were performed on admission and the seventh day of the first control after a period of fasting lasting at least eight hours. Systemic neurological and otorhinolaryngological examinations were performed.

Whole blood analysis results were evaluated retrospectively. The NLR was calculated by dividing the neutrophil count by the lymphocyte count per microlitre (NLR = neutrophils (×10^3 per µl) / lymphocytes (×10^3 per µl)). PLR ratio was calculated by dividing platelet count by the lymphocyte count per microlitre.

Statistical analysis was performed using SPSS, version 19.0 for Windows (IBM, Armonk, NY). Descriptive data were expressed as means and standard deviation. The Kolmogorov-Smirnov test was used for a normality test. Mann-Whitney-U tests were used to evaluate differences between the groups. The Wilcoxon test was used to evaluate differences between whole blood count parameters on admission, and on the seventh day of admission, within groups Pearson, correlation analysis was used to evaluate differences between House-Brackman Staging system and parameters. For each test, a P value of 0.05 or less was treated as statistically significant.

Results

Twenty-eight patients were included in the study (16 males (57%), 12 females (43%). The mean age was 29.5 ± 10.5 (18–62).

Socio-demographic data and the entire blood results of the Bells Palsy population are demonstrated in Table 1. On admission, the NLR was 1.7 ± 1.2 (Fig. 1). The mean absolute neutrophil count was 6100 ± 900/mm^3, and the mean absolute lymphocyte count was 3800 ± 1200/mm^3. PLR was 129.4 ± 15.4; MPV was 8.2 ± 0.4 FL and RDW was 12.9 ± 0.6 on admission. On the seventh day of admission, the NLR was 1.5 ± 0.9. The mean absolute neutrophil count was 5900 ± 900/mm^3, and the mean absolute lymphocyte count was 3000 ± 800/mm^3. PLR was 135.2 ± 19, MPV was 8.4 ± 0.3 FL and RDW was 12.2 ± 0.4 (Table 1).

Figure 1: NLR and Bells Palsy can be seen on Figure(NLR: Neutrophil to Lymphocyte Ratio)

On admission, NLR was 0.9 ± 0.2, the mean absolute neutrophil count was 4400 ± 1100/mm^3, and the mean absolute lymphocyte count was 3900 ± 1200/mm^3. PLR was 139.4 ± 19.4; MPV was 8.4 ± 0.4 FL and RDW was 12.5 ± 0.6 on a control group. On the seventh day of admission, NLR was 1.1 ± 0.1, the mean absolute neutrophil count was 4100 ± 300/mm^3, and the mean absolute lymphocyte count was 4000 ± 600/mm^3. PLR was 134.2 ± 12, MPV was 8.1 ± 0.3 FL and RDW was 12.1 ± 0.4 (Table 2).
Statistically significant changes between the neutrophil count, the lymphocyte count, NLR, PLR, MPV and RDW were not determined using the measurements made in the one week interval between examinations of the Bells Palsy group (p = 0.3, p = 0.37, p = 0.2, p = 0.07, p = 0.6, and p = 0.7, respectively) (Table 2).

Statistically, significant changes in the neutrophil count and NLR were determined in the measurements between Bells Palsy and control group (p = 0.013, p = 0.016 respectively) on admission (Table 3). There is still statistically significant difference on 7. Day of admission (p = 0.016, p = 0.03 respectively).

Significant changes were not observed in haemoglobin and haematocrit values, lymphocyte counts, PLR, MPV and RDW measurements between Bells Palsy and control Group (p = 0.2, p = 0.67, p = 0.42, p = 0.65, p = 0.67, p = 0.8 respectively) on first admission. There is still no significant change on 7, day of admission between groups.

Significant changes were not observed in NLR, PLR, MPV and RDW measurements in Bells Palsy group between House-Brackmann Staging (p = 0.84, p = 0.79, p = 0.63, p = 0.64 respectively). A grade of the disease and NLR measurements had no statistically significant connection.

Discussion

The most important outcome of the present study was that the NLR and neutrophil count was significantly higher in patients with Bells Palsy than in control Group; this ratio was higher in the Bells Palsy than in the control group in the first week after admission. The second most important result of this study was the demonstration of statistically not significant changes on PLR; MPV; RDW measurements. The third important result of the study is there is no significant change in measures between House-Brackmann classifications of Bells palsy. Therefore the NLR value does not change in the different grades of disease.

There were several causative aetiological factors for Bells Palsy. Viral infections and inflammation, vascular neuritis, peripheral vascular diseases, thromboembolism and microvascular circulatory impairment, immunological diseases were known factors [1]. Viruses were the most common aetiological factors, but it is not enough to determine the whole aetiology. From the microvascular circulatory impairment point of view, neuritis was associated with vascular inflammation.

Whole blood analysis is associated with the general condition of the patient. Higher neutrophil counts can be associated with inflammatory conditions. Lower lymphocyte count can be associated with higher organic stress [3]. The NLR is an inflammatory marker that has been studied in...
recent years, for the differential diagnosis and follows up of certain diseases. The NLR was evaluated in, acute hearing loss, Bell’s palsy and vertigo in the practice of Otorhinolaryngology [8, 9]. The NLR as an inflammatory marker was shown to be associated with the prognosis of cancer of the body [10].

The presence of an elevated NLR in Bell’s Palsy was demonstrated via the literature search [11-13]. NLR ratio was higher in 656 patients Bell’s Palsy group in a study [12]. NLR was also higher in Bell’s Palsy patients and another study by Ozler et al. NLR measurements were correlated with the disease in this study [13]. Atan et al. (2015) revealed that NLR was higher in 99 Bell’s palsy group, but the NLR was not correlated with House-Brackman grade [14]. Eryilmaz et al. (2015) revealed that NLR was higher in paediatric Bells palsy group, but the NLR was not correlated with House-Brackman grade [11]. There was no consensus on literature about the correlation of NLR and grade of the disease in the literature.

MPV is a parameter indicating platelet volume. It can be correlated with microvascular thrombotic diseases. MPV correlation with stroke is revealed in the literature [15]. In this perspective, MPV can be associated with microvascular obstruction. Correlation with MPV levels and Bells palsy was not documented in the literature [12]. In our study MPV was no statistically significantly higher in Bell’s patients.

RDW is a parameter indicating height and heterogeneity of the erythrocyte volume [16]. This parameter can increase in anaemia, myelodysplastic syndromes, haemolytic diseases and cause microvascular thrombotic diseases [16]. Correlation of RDW and migraine is posted in the literature [17]. Also, there are studies about the relation of RDW with coronary diseases in the literature [18, 19]. There is no actual study about RDW and Bell’s Palsy in the literature. In our study RDW was no statistically significantly higher in Bell’s palsy patients.

PLR is also a parameter used as NLR widely in the literature nowadays. There are studies that have been done with the values PLR in the myocardial infarct [20]. PLR is posted in gastric and oesophageal cancer in the literature [21]. PLR is associated with sudden hearing loss in the literature [8]. There are few investigations about Bells Palsy and PLR in literature. In our study PLR was no statistically significantly higher in Bells palsy patients.

The limitations of our study were the retrospective design of the study, the limited number of cases and the limited time available for the second evaluation. Further prospective studies to evaluate the association between the NLR and both the diagnosis and prognosis of Bells palsy are needed.

In the present study, the NLR and neutrophil count were significantly higher in patients with Bell’s Palsy than in those with a control group. There is statistically significant change between NLR and Grade of the disease. Our study strengthened the inflammation theory as an aetiological factor for Bell’s Palsy rather than ischemic theory. Factors can be associated with peripheral vascular diseases and thromboembolism such as PLR, MPV, and RDW was normal in our study regarding control group. We aimed to investigate the whole blood parameters in Bell’s Palsy to evaluate the mean and connection with Bell’s Palsy herein.
